How to Ride a Motorcycle With Parts Missing (on you, not the bike)
Adaptive Modifications for Amputee Motorcycling

You’ve seen them cruising down a winding highway, heard the roar of pipes on the boulevard, dreamed of the thrill and freedom of a motorcycle, and wondered; “Can I still ride a motorcycle after my amputation?”

The answer is an enthusiastic “Yes!” In this article, we will review common motorcycle modifications that can help an amputee rider get back on the road and, just as importantly, how to prepare yourself.

Getting Started
Getting your motorcycle ready for amputee riding isn’t necessarily difficult. You merely need to understand how the controls on the motorcycle operate and how to modify them to work with your prosthesis.

An adaptive rider’s best friend is a local cycle shop with a craftsman who is able to modify your motorcycle, because there are no formal adaptive motorcycling organizations in the U.S. The market is simply too small to find most motorcycle adaptations “off the shelf,” so you may need to customize your bike for your specific needs and abilities. Let’s start by looking at how a rider uses the controls on a motorcycle and some common modifications for amputees.

Left Leg
On a standard motorcycle, the left foot operates the gear shifter by lifting up and pushing down with the toes. Riders with a below-knee (BK) prosthesis can modify the shift lever by adding a heel extension to allow changing gears by both pushing down with the heel and pushing down at the toe position. This system already comes standard on some cruiser models like the Harley-Davidson. Alternatively, the shifter can be moved to the right side, as it is used to be on older British bikes. A brake system that automatically interconnects the front and rear brakes and eliminates the need for these changes.

Above-Knee Considerations
Above-knee (AK) riders have two challenges to cope with: keeping the bike upright while stopped, and operating the side stand. Solutions for these challenges include choosing a prosthetic knee that is stable in an extended position and linking the side stand to a hand lever extender below the tank. Many AK riders eliminate these issues by riding a motorcycle with a sidecar or a trike, both of which are more stable yet allow the freedom of motorcycling.

Right Leg
Most motorcycles operate the real wheel brake with a toe lever on the right side. Modification options for right leg amputees include either operating a modified right brake pedal with the prosthesis, moving the brake to the left side, or mounting a second hand brake lever in tandem with the front brake lever on the handlebar. BMW and many other modern motorcycles now come with an anti-lock brake system that automatically interconnects the front and rear brakes and eliminates the need for these changes.

Other Options for Leg Amputees
An alternative to the expense and hassle of modifying a standard motorcycle is to choose one with automatic transmission, where all the bike’s functions are operated by hand controls. Great options vary from the classic Italian Vespa scooter, the “super scooter” Honda Silver Wing and Suzuki 650 Burgman models that have the look and performance of modern motorcycles, to the Ridley cruiser, which has the sound and appearance of a custom V-twin.

Arm Amputees
Arm amputees, even more than leg amputees, are faced with the choice of modifying either the motorcycle or their prosthesis. Changing the motorcycle involves rerouting the standard brake, throttle or clutch controls so they can be operated with one hand. Customized prosthetic modifications allow the rider to engage the brake or clutch with a specialized terminal device designed specifically for the motorcycle. Bike kits and prosthetic solutions are available on the Internet (see Related Resources). Additional recommendations for arm amputees include a front steering dampener and using Velcro® on the glove.
Getting on the Road

Riding a motorcycle is a thoroughly exhilarating and fun experience. But, along with the thrills come some additional risks and responsibilities. Before starting adaptive motorcycling, consider a Motorcycle Safety Foundation (MSF) class to learn the rules of the road, and check with your state motor vehicle department to find out if there are additional testing/driving requirements for adaptive riders. Buy the best helmet that is comfortable for you to wear, and wear it every time you ride. Start on side roads away from traffic, and move up to higher speeds and traffic as your skills progress.

See you on the road, and keep the shiny side up!
